

Re-analysis Summary Report for Peer-evaluation

Paper ID: Christensen_EurJournPersonality_2018_8R9d

Re-analyst's ID: ghz5e

Your task

As a peer-evaluator, for this paper you are asked to judge whether the analyst's applied analytical choices for Task 1 and Task 2 are acceptable. By acceptable, we mean that the analysis pipeline is within the variations that could be considered appropriate by the scientific community in addressing the given analytical task. In addition, for Task 1, we ask you to judge whether the reported conclusion adequately follows from the results of the analysis; whether the co-analyst's self-categorization of the result is adequate. Although, you are not required, it would be appreciated, if you could execute the accompanying analysis code to check any mismatch between the results of the analysis and the reported results.

For both tasks, you should provide your evaluation via this survey: <https://forms.gle/EAREaC6JjN2PWFfR6>

The re-analyst's task

The re-analyst was instructed to assess the following claim of the original authors:

... the high openness to experience group's network was more interconnected ... than the low openness to experience group (p. 480.)

The corresponding article

Here you can find the original article: https://osf.io/6ve3b/?view_only=c874fcf097644e82a320679d4641163a and the original data: https://osf.io/6zh34/?view_only=3e5bfed2e1f041dbbb4376e9c0c5f70b

They are provided only as context of the re-analysis.

In Task 1, the analyst was asked to conduct the analysis without any restrictions. Here, the analyst reported the following steps and results of the analysis:

I tested the authors' claim that the high openness to experience group's network was more interconnected than the low openness to experience group. I computed three measures: ASPL (short path lengths indicate increased interconnectivity); CC (clustering coefficient); and Q (modularity). Partial bootstrap network test show the between-group difference is significant. High: ASPL = 3.7573888; CC = 0.7369707; Q = 0.6653330. Low: ASPL = 4.2964108; CC = 0.7267746; Q = 0.6738231.

The analyst's conclusion: These results are consistent with the claim that the high openness to experience group's network was more interconnected than the low openness to experience group.

The analyst's categorization of the result:

The results show evidence for the relationship/effect as described in the claim provided in your task

In Task 2, the analysts received the following instruction to conduct the analysis:

In the partial network that you use, the rate of nodes remaining should be 90%.

Here, the analyst reported the following steps and results of the analysis:

I tested the claim that the high openness to experience group's network was more interconnected than the low openness to experience group (p. 480.). I calculated semantic network measures ASPL (average shortest path length), CC (clustering coefficient), and Q (modularity) for High and Low openness to experience groups. I used a partial network bootstrapped approach to test groups differences with 50%, 60%, 70%, 80%, and 90% bootstrap partitions.

Analysis language/software/code (optional to check):

Task 1: R

Task 2: R
