

Re-analysis Summary Report for Peer-evaluation

Paper ID: McDevitt_JournPoliEco_2014_yQeR

Re-analyst's ID: daa9c

Your task

As a peer-evaluator, for this paper you are asked to judge whether the analyst's applied analytical choices for Task 1 and Task 2 are acceptable. By acceptable, we mean that the analysis pipeline is within the variations that could be considered appropriate by the scientific community in addressing the given analytical task. In addition, for Task 1, we ask you to judge whether the reported conclusion adequately follows from the results of the analysis; whether the co-analyst's self-categorization of the result is adequate. Although, you are not required, it would be appreciated, if you could execute the accompanying analysis code to check any mismatch between the results of the analysis and the reported results.

For both tasks, you should provide your evaluation via this survey: <https://forms.gle/EAREaC6JjN2PWFfR6>

The re-analyst's task

The re-analyst was instructed to assess the following claim of the original authors:

The average plumbing firm whose name begins with A or a number receives... more service complaints than other firms ...(p. 909.)

The corresponding article

Here you can find the original article: https://osf.io/6fusy/?view_only=c874fcf097644e82a320679d4641163a and the original data: https://osf.io/z7mfu/?view_only=277b7d18bb24436eb5cfca69a07eb07a

They are provided only as context of the re-analysis.

In Task 1, the analyst was asked to conduct the analysis without any restrictions. Here, the analyst reported the following steps and results of the analysis:

The paper describes where “the primary data” came from, but did not make that raw data available. I converted the provided Stata (.dta) formats to .csv with Pandas in order to be able to read them. I found a file called “final_data” that seemed to contain the cleaned data, which matched a Table in the Appendix for number of records. The assigned claim only necessitated keeping two columns, so the analysis was relatively straightforward.

The analyst's conclusion: On average, plumbing firms in Illinois with names beginning with an A, number, or symbol have 5x more complaints than those whose names do not.

The analyst's categorization of the result:

The results show evidence for the relationship/effect as described in the claim provided in your task

In Task 2, the analysts received the following instruction to conduct the analysis:

Use only the data of Illinois Plumbing Firms in your model. Do not restrict your sample to those firms that

serve the metro Chicago area. Do not include the reviews received via yelp.com, Angie's List, and Consumer's Checkbook into your analysis. You should use the overall complaints number instead of complaints per employee.

Here, the analyst reported the following steps and results of the analysis:

In JMP, open file "final_data.dta.csv" File was created in Multi100 Step 1 by converting from Stata format to .csv using pandas Change "first_A" variable from Continuous to Nominal variable type Run code provided in JMP Script file to get t-test, dual-sided 0.0001

Analysis language/software/code (optional to check):

Task 1: Python, JMP

Task 2: JMP
